The FMB algorithm
An intersection detection algorithm for 2D/3D cuboid and tetrahedron based on the Fourier-Motzkin elimination method

P. Baillehache

November 23, 2019

Abstract

In this paper I introduce how to perform intersection detection of pair of cuboid/tetrahedron in 2D and 3D by using the Fourier-Motzkin elimination method. The mathematical definition and solution of the problem in the two first sections is followed by the algorithm of the solution and its implementation in the C programming language in the two following sections. The last two sections introduce the validation and qualification of the FMB algorithm against the SAT algorithm.

1 Definition of the problem

1.1 Static case

In this paper I'll use the term "Frame" to speak indifferently of cuboid and tetrahedron.

The two Frames are represented as a vector origin and a number of component vectors equal to the dimension D of the space where live the Frames. Each vector is of dimension equal to D.

Lets call $\mathbb{A}$ and $\mathbb{B}$ the two Frames tested for intersection. If A and B are two cuboids:

$$\mathbb{A} = \left\{ \overrightarrow{X} \in [0.0, 1.0]^D, \overrightarrow{O_{\mathbb{A}}} + C_{\mathbb{A}}.\overrightarrow{X} \right\} \tag{1}$$

$$\mathbb{B} = \left\{ \overrightarrow{X} \in [0.0, 1.0]^D, \overrightarrow{O_{\mathbb{B}}} + C_{\mathbb{B}}.\overrightarrow{X} \right\} \tag{2}$$

where $O_{\mathbb{A}}$ is the origin of $\mathbb{A}$ and $C_{\mathbb{A}}$ is the matrix of the components of A (one component per column). Idem for $\overrightarrow{O_{\mathbb{B}}}$ and $C_{\mathbb{B}}$.

If $\mathbb{A}$ and $\mathbb{B}$ are two tetrahedrons:

$$\mathbb{A} = \left\{ \overrightarrow{X} \in [0.0, 1.0]^D, \sum_{i=0}^{D-1} Xi \leq 1.0, \overrightarrow{O_{\mathbb{A}}} + C_{\mathbb{A}}.\overrightarrow{X} \right\} \tag{3}$$

$$\mathbb{B} = \left\{ \overrightarrow{X} \in [0.0, 1.0]^D, \sum_{i=0}^{D-1} Xi \leq 1.0, \overrightarrow{O_{\mathbb{B}}} + C_{\mathbb{B}}.\overrightarrow{X} \right\} \tag{4}$$

I'll assume the Frames are well formed, i.e. their components matrix is invertible. It is then possible to express $\mathbb{B}$ in $\mathbb{A}$'s coordinates system, noted as $\mathbb{B}_{\mathbb{A}}$. If $\mathbb{B}$ is a cuboid:

$$\mathbb{B}_{\mathbb{A}} = \left\{ \overrightarrow{X} \in [0.0, 1.0]^D, C_{\mathbb{A}}^{-1}.(\overrightarrow{O_{\mathbb{B}}} - \overrightarrow{O_{\mathbb{A}}} + C_{\mathbb{B}}.\overrightarrow{X}) \right\} \tag{5}$$

If $\mathbb{B}$ is a tetrahedron:

$$\mathbb{B}_{\mathbb{A}} = \left\{ \overrightarrow{X} \in [0.0, 1.0]^D, \sum_{i=0}^{D-1} Xi \leq 1.0, C_{\mathbb{A}}^{-1}.(\overrightarrow{O_{\mathbb{B}}} - \overrightarrow{O_{\mathbb{A}}} + C_{\mathbb{B}}.\overrightarrow{X}) \right\} \quad (6)$$

$\mathbb{A}$ in its own coordinates system becomes, for a cuboid:

$$\mathbb{A}_{\mathbb{A}} = \left\{ \overrightarrow{X} \in [0.0, 1.0]^D \right\} \quad (7)$$

and for a tetrahedron:

$$\mathbb{A}_{\mathbb{A}} = \left\{ \overrightarrow{X} \in [0.0, 1.0]^D, \sum_{i=0}^{D-1} Xi \leq 1.0 \right\} \quad (8)$$

The intersection of $\mathbb{A}$ and $\mathbb{B}$ in $\mathbb{A}$'s coordinates sytem, can then be expressed as follow.

If $\mathbb{A}$ and $\mathbb{B}$ are two cuboids:

$$\left\{ \overrightarrow{X} \in [0.0, 1.0]^D, C_{\mathbb{A}}^{-1}. \left(\overrightarrow{O_{\mathbb{B}}} - \overrightarrow{O_{\mathbb{A}}} + C_{\mathbb{B}}.\overrightarrow{X} \right) \cap [0.0, 1.0]^D \right\} \quad (9)$$

If $\mathbb{A}$ is a cuboid and $\mathbb{B}$ is a tetrahedron:

$$\left\{ \begin{array}{c} \overrightarrow{X} \in [0.0, 1.0]^D, \sum_{i=0}^{D-1} Xi \leq 1.0, \\ C_{\mathbb{A}}^{-1}. \left(\overrightarrow{O_{\mathbb{B}}} - \overrightarrow{O_{\mathbb{A}}} + C_{\mathbb{B}}.\overrightarrow{X} \right) \cap [0.0, 1.0]^D \end{array} \right\} \quad (10)$$

If $\mathbb{A}$ is a tetrahedron and $\mathbb{B}$ is a cuboid:

$$\left\{ \begin{array}{c} \overrightarrow{X} \in [0.0, 1.0]^D, C_{\mathbb{A}}^{-1}. \left(\overrightarrow{O_{\mathbb{B}}} - \overrightarrow{O_{\mathbb{A}}} + C_{\mathbb{B}}.\overrightarrow{X} \right) \cap [0.0, 1.0]^D \\ \sum_{i=0}^{D-1} \left(C_{\mathbb{A}}^{-1}. \left(\overrightarrow{O_{\mathbb{B}}} - \overrightarrow{O_{\mathbb{A}}} + C_{\mathbb{B}}.\overrightarrow{X} \right) \right)_i \leq 1.0 \end{array} \right\} \quad (11)$$

If $\mathbb{A}$ and $\mathbb{B}$ are two tetrahedrons:

$$\left\{ \begin{array}{c} \overrightarrow{X} \in [0.0, 1.0]^D, \sum_{i=0}^{D-1} Xi \leq 1.0 \\ C_{\mathbb{A}}^{-1}.(\overrightarrow{O_{\mathbb{B}}} - \overrightarrow{O_{\mathbb{A}}} + C_{\mathbb{B}}.\overrightarrow{X}) \cap [0.0, 1.0]^D \\ \sum_{i=0}^{D-1} \left(C_{\mathbb{A}}^{-1}. \left(\overrightarrow{O_{\mathbb{B}}} - \overrightarrow{O_{\mathbb{A}}} + C_{\mathbb{B}}.\overrightarrow{X} \right) \right)_i \leq 1.0 \end{array} \right\} \quad (12)$$

These can in turn be expressed as systems of linear inequations as follows, given the two shortcuts $\overrightarrow{O_{\mathbb{B}_{\mathbb{A}}}} = C_{\mathbb{A}}^{-1}.(\overrightarrow{O_{\mathbb{B}}} - \overrightarrow{O_{\mathbb{A}}})$ and $C_{\mathbb{B}_{\mathbb{A}}} = C_{\mathbb{A}}^{-1}.C_{\mathbb{B}}$, and the notation M_{rc} for the element at column c and row r of the matrix M.

If $\mathbb{A}$ and $\mathbb{B}$ are two cuboids:

$$\begin{cases} X_0 \leq 1.0 \\ -X_0 \leq 0.0 \\ ... \\ X_{D-1} \leq 1.0 \\ -X_{D-1} \leq 0.0 \\ \sum_{i=0}^{D-1} C_{\mathbb{B}_\mathbb{A}0i} X_i \leq 1.0 - O_{\mathbb{B}_\mathbb{A}0} \\ -\sum_{i=0}^{D-1} C_{\mathbb{B}_\mathbb{A}0i} X_i \leq -O_{\mathbb{B}_\mathbb{A}0} \\ ... \\ \sum_{i=0}^{D-1} C_{\mathbb{B}_\mathbb{A}(D-1)i} X_i \leq 1.0 - O_{\mathbb{B}_\mathbb{A}(D-1)} \\ -\sum_{i=0}^{D-1} C_{\mathbb{B}_\mathbb{A}(D-1)i} X_i \leq -O_{\mathbb{B}_\mathbb{A}(D-1)} \end{cases} \tag{13}$$

If $\mathbb{A}$ is a cuboid and $\mathbb{B}$ is a tetrahedron:

$$\begin{cases} -X_0 \leq 0.0 \\ ... \\ -X_{D-1} \leq 0.0 \\ \sum_{i=0}^{D-1} C_{\mathbb{B}_\mathbb{A}0i} X_i \leq 1.0 - O_{\mathbb{B}_\mathbb{A}0} \\ -\sum_{i=0}^{D-1} C_{\mathbb{B}_\mathbb{A}0i} X_i \leq -O_{\mathbb{B}_\mathbb{A}0} \\ ... \\ \sum_{i=0}^{D-1} C_{\mathbb{B}_\mathbb{A}(D-1)i} X_i \leq 1.0 - O_{\mathbb{B}_\mathbb{A}(D-1)} \\ -\sum_{i=0}^{D-1} C_{\mathbb{B}_\mathbb{A}(D-1)i} X_i \leq -O_{\mathbb{B}_\mathbb{A}(D-1)} \\ \sum_{i=0}^{D-1} Xi \leq 1.0 \end{cases} \tag{14}$$

If $\mathbb{A}$ is a tetrahedron and $\mathbb{B}$ is a cuboid:

$$\begin{cases} X_0 \leq 1.0 \\ -X_0 \leq 0.0 \\ ... \\ X_{D-1} \leq 1.0 \\ -X_{D-1} \leq 0.0 \\ -\sum_{i=0}^{D-1} C_{\mathbb{B}_\mathbb{A}0i} X_i \leq -O_{\mathbb{B}_\mathbb{A}0} \\ ... \\ \sum_{i=0}^{D-1} C_{\mathbb{B}_\mathbb{A}(D-1)i} X_i \leq 1.0 - O_{\mathbb{B}_\mathbb{A}(D-1)} \\ -\sum_{i=0}^{D-1} C_{\mathbb{B}_\mathbb{A}(D-1)i} X_i \leq -O_{\mathbb{B}_\mathbb{A}(D-1)} \\ \sum_{j=0}^{D-1} \left(\sum_{i=0}^{D-1} \left(C_{\mathbb{B}_\mathbb{A}ji} \right) X_i \right) \leq 1.0 - \sum_{i=0}^{D-1} O_{\mathbb{B}_\mathbb{A}i} \end{cases} \tag{15}$$

If $\mathbb{A}$ and $\mathbb{B}$ are two tetrahedrons:

$$\left\{\begin{array}{c} -X_0 \leq 0.0 \\ ... \\ -X_{D-1} \leq 0.0 \\ -\sum_{i=0}^{D-1} C_{\mathbb{B}_\mathbb{A} 0i} X_i \leq -O_{\mathbb{B}_\mathbb{A} 0} \\ ... \\ \sum_{i=0}^{D-1} C_{\mathbb{B}_\mathbb{A}(D-1)i} X_i \leq 1.0 - O_{\mathbb{B}_\mathbb{A}(D-1)} \\ -\sum_{i=0}^{D-1} C_{\mathbb{B}_\mathbb{A}(D-1)i} X_i \leq -O_{\mathbb{B}_\mathbb{A}(D-1)} \\ \sum_{i=0}^{D-1} Xi \leq 1.0 \\ \sum_{j=0}^{D-1} \left(\sum_{i=0}^{D-1} \left(C_{\mathbb{B}_\mathbb{A} ji} \right) X_i \right) \leq 1.0 - \sum_{i=0}^{D-1} O_{\mathbb{B}_\mathbb{A} i} \end{array}\right. \tag{16}$$

1.2 Dynamic case

If the frames $\mathbb{A}$ and $\mathbb{B}$ are moving linearly along the vectors $\overrightarrow{V_\mathbb{A}}$ and $\overrightarrow{V_\mathbb{B}}$ respectively during the interval of time $t \in [0.0, 1.0]$, the above definition of the problem is modified as follow.

If A and B are two cuboids:

$$\mathbb{A} = \left\{ \overrightarrow{X} \in [0.0, 1.0]^D, t \in [0.0, 1.0], \overrightarrow{O_\mathbb{A}} + C_\mathbb{A}.\overrightarrow{X} + \overrightarrow{V_\mathbb{A}.t} \right\} \tag{17}$$

$$\mathbb{B} = \left\{ \overrightarrow{X} \in [0.0, 1.0]^D, t \in [0.0, 1.0], \overrightarrow{O_\mathbb{B}} + C_\mathbb{B}.\overrightarrow{X} + \overrightarrow{V_\mathbb{B}}.t \right\} \tag{18}$$

where $O_\mathbb{A}$ is the origin of $\mathbb{A}$ and $C_\mathbb{A}$ is the matrix of the components of A (one component per column). Idem for $\overrightarrow{O_\mathbb{B}}$ and $C_\mathbb{B}$.

If $\mathbb{A}$ and $\mathbb{B}$ are two tetrahedrons:

$$\mathbb{A} = \left\{ \overrightarrow{X} \in [0.0, 1.0]^D, t \in [0.0, 1.0], \sum_{i=0}^{D-1} Xi \leq 1.0, \overrightarrow{O_\mathbb{A}} + C_\mathbb{A}.\overrightarrow{X} + \overrightarrow{V_\mathbb{A}}.t \right\} \tag{19}$$

$$\mathbb{B} = \left\{ \overrightarrow{X} \in [0.0, 1.0]^D, t \in [0.0, 1.0], \sum_{i=0}^{D-1} Xi \leq 1.0, \overrightarrow{O_\mathbb{B}} + C_\mathbb{B}.\overrightarrow{X} + \overrightarrow{V_\mathbb{B}}.t \right\} \tag{20}$$

If $\mathbb{B}$ is a cuboid, $\mathbb{B}_\mathbb{A}$ becomes:

$$\mathbb{B}_\mathbb{A} = \left\{ \begin{array}{c} \overrightarrow{X} \in [0.0, 1.0]^D, t \in [0.0, 1.0], \\ C_\mathbb{A}^{-1}.\left(\overrightarrow{O_\mathbb{B}} - \overrightarrow{O_\mathbb{A}} + C_\mathbb{B}.\overrightarrow{X} + \left(\overrightarrow{V_\mathbb{B}} - \overrightarrow{V_\mathbb{A}} \right) .t \right) \end{array} \right\} \tag{21}$$

If $\mathbb{B}$ is a tetrahedron:

$$\mathbb{B}_{\mathbb{A}} = \left\{ \begin{array}{c} \overrightarrow{X} \in [0.0, 1.0]^D, t \in [0.0, 1.0], \sum_{i=0}^{D-1} Xi \leq 1.0, \\ C_{\mathbb{A}}^{-1}.\left(\overrightarrow{O_{\mathbb{B}}} - \overrightarrow{O_{\mathbb{A}}} + C_{\mathbb{B}}.\overrightarrow{X} + \left(\overrightarrow{V_{\mathbb{B}}} - \overrightarrow{V_{\mathbb{A}}}\right).t\right) \end{array} \right\} \tag{22}$$

$\mathbb{A}$ in its own coordinates system has the same definition as in the static case. For a cuboid:

$$\mathbb{A}_{\mathbb{A}} = \left\{ \overrightarrow{X} \in [0.0, 1.0]^D \right\} \tag{23}$$

and for a tetrahedron:

$$\mathbb{A}_{\mathbb{A}} = \left\{ \overrightarrow{X} \in [0.0, 1.0]^D, \sum_{i=0}^{D-1} Xi \leq 1.0 \right\} \tag{24}$$

The intersection of $\mathbb{A}$ and $\mathbb{B}$ in $\mathbb{A}$'s coordinates sytem, can then be expressed as follow.

If $\mathbb{A}$ and $\mathbb{B}$ are two cuboids:

$$\left\{ \begin{array}{c} \overrightarrow{X} \in [0.0, 1.0]^D, t \in [0.0, 1.0], \\ C_{\mathbb{A}}^{-1}.\left(\overrightarrow{O_{\mathbb{B}}} - \overrightarrow{O_{\mathbb{A}}} + C_{\mathbb{B}}.\overrightarrow{X} + \left(\overrightarrow{V_{\mathbb{B}}} - \overrightarrow{V_{\mathbb{A}}}\right).t\right) \cap [0.0, 1.0]^D \end{array} \right\} \tag{25}$$

If $\mathbb{A}$ is a cuboid and $\mathbb{B}$ is a tetrahedron:

$$\left\{ \begin{array}{c} \overrightarrow{X} \in [0.0, 1.0]^D, t \in [0.0, 1.0], \sum_{i=0}^{D-1} Xi \leq 1.0, \\ C_{\mathbb{A}}^{-1}.\left(\overrightarrow{O_{\mathbb{B}}} - \overrightarrow{O_{\mathbb{A}}} + C_{\mathbb{B}}.\overrightarrow{X} + \left(\overrightarrow{V_{\mathbb{B}}} - \overrightarrow{V_{\mathbb{A}}}\right).t\right) \cap [0.0, 1.0]^D \end{array} \right\} \tag{26}$$

If $\mathbb{A}$ is a tetrahedron and $\mathbb{B}$ is a cuboid:

$$\left\{ \begin{array}{c} \overrightarrow{X} \in [0.0, 1.0]^D, t \in [0.0, 1.0], \\ C_{\mathbb{A}}^{-1}.\left(\overrightarrow{O_{\mathbb{B}}} - \overrightarrow{O_{\mathbb{A}}} + C_{\mathbb{B}}.\overrightarrow{X} + \left(\overrightarrow{V_{\mathbb{B}}} - \overrightarrow{V_{\mathbb{A}}}\right).t\right) \cap [0.0, 1.0]^D \\ \sum_{i=0}^{D-1} \left(C_{\mathbb{A}}^{-1}.\left(\overrightarrow{O_{\mathbb{B}}} - \overrightarrow{O_{\mathbb{A}}} + C_{\mathbb{B}}.\overrightarrow{X}\right)\right)_i \leq 1.0 \end{array} \right\} \tag{27}$$

If $\mathbb{A}$ and $\mathbb{B}$ are two tetrahedrons:

$$\left\{ \begin{array}{c} \overrightarrow{X} \in [0.0, 1.0]^D, t \in [0.0, 1.0], \sum_{i=0}^{D-1} Xi \leq 1.0 \\ C_{\mathbb{A}}^{-1}.(\overrightarrow{O_{\mathbb{B}}} - \overrightarrow{O_{\mathbb{A}}} + C_{\mathbb{B}}.\overrightarrow{X} + \left(\overrightarrow{V_{\mathbb{B}}} - \overrightarrow{V_{\mathbb{A}}}\right).t) \cap [0.0, 1.0]^D \\ \sum_{i=0}^{D-1} \left(C_{\mathbb{A}}^{-1}.\left(\overrightarrow{O_{\mathbb{B}}} - \overrightarrow{O_{\mathbb{A}}} + C_{\mathbb{B}}.\overrightarrow{X}\right)\right)_i \leq 1.0 \end{array} \right\} \tag{28}$$

2 Solution

2.1 Fourier-Motzkin elimination method

The Fourier-Motzkin elimination method has been introduced by J.J.-B. Fourier in 1827 [1], and described in the Ph.D. thesis of T.S. Motzkin in 1936 [2]. This is a generalization of the Gaussian elimination method to linear systems of inequalities. This method consists of eliminating one variable of the system and rewrite a new system accordingly. Then the elimination operation is repeated on another variable in the new system, and so on until we obtain a trivial system with only one variable. From there, a solution for each variable can be obtained if it exists. The variable elimination is performed as follow.
Lets write the linear system $\mathcal{I}$ of m inequalities and n variables as

$$\left\{\begin{array}{lllll} a_{11}.x_1 & +a_{12}.x_2 & +\cdots & +a_{1n}.x_n & \leq b_1 \\ a_{21}.x_1 & +a_{22}.x_2 & +\cdots & +a_{2n}.x_n & \leq b_2 \\ & & \vdots & & \\ a_{m1}.x_1 & +a_{m2}.x_2 & +\cdots & +a_{mn}.x_n & \leq b_m \end{array}\right. \tag{29}$$

with

$$\begin{array}{c} i \in 1, 2, ..., m \\ j \in 1, 2, ..., n \\ x_i \in \mathbb{R} \\ a_{ij} \in \mathbb{R} \\ b_j \in \mathbb{R} \end{array} \tag{30}$$

To eliminate the first variable x_1, lets multiply each inequality by $1.0/|a_{i1}|$ where $a_{i1} \neq 0.0$. The system becomes

$$\left\{\begin{array}{lllll} x_1 & +a'_{i2}.x_2 & +\cdots & +a'_{in}.x_n & \leq b'_i \quad (i \in \mathcal{I}_+) \\ & a_{i2}.x_2 & +\cdots & +a_{in}.x_n & \leq b_i \quad (i \in \mathcal{I}_0) \\ -x_1 & +a'_{i2}.x_2 & +\cdots & +a'_{in}.x_n & \leq b'_i \quad (i \in \mathcal{I}_-) \end{array}\right. \tag{31}$$

where

$$\mathcal{I}_+ = \{i : a_{i1} > 0.0\}$$
$$\mathcal{I}_0 = \{i : a_{i1} = 0.0\}$$
$$\mathcal{I}_- = \{i : a_{i1} < 0.0\}$$
$$a'_{ij} = a_{ij}/|a_{i1}|$$
$$b'_i = b_i/|a_{i1}|$$

Then $x_1, x_2, \cdots, x_n \in \mathbb{R}^n$ is a solution of $\mathcal{I}$ if and only if

$$\begin{cases} \sum_{j=2}^{n}((a'_{kj} + a'_{lj}).x_j) \leq b'_k + b'_l & (k \in \mathcal{I}_+, l \in \mathcal{I}_-) \\ \sum_{j=2}^{n}(a_{ij}.x_j) \leq b_i & i \in \mathcal{I}_0 \end{cases} \tag{32}$$

and

$$\max_{l \in \mathcal{I}_-}(\sum_{j=2}^{n}(a'_{lj}.x_j) - b'_l) \leq x_1 \leq \min_{k \in \mathcal{I}_+}(b'_k - \sum_{j=2}^{n}(a'_{kj}.x_j)) \tag{33}$$

The same method is then applied on this new system to eliminate the second variable x_2, and so on until we reach the inequality

$$\max_{l \in \mathcal{I}''^{\cdots'}_-}(-b''^{\cdots'}_l) \leq x_n \leq \min_{k \in \mathcal{I}''^{\cdots'}_+}(b''^{\cdots'}_k) \tag{34}$$

If this inequality has no solution, then neither the system $\mathcal{I}$. If it has a solution, the minimum and maximum are the bounding values for the variable x_n. One can get a particular solution to the system $\mathcal{I}$ by choosing a value for x_n between these bounding values, which allow us to set a particular value for the variable x_{n-1}, and so on back up to x_1.

2.2 Application of the Fourier-Motzkin method to the intersection problem

The Fourier-Motzkin method can be directly applied to obtain the bounds of each variable, if the system has a solution. If the system has no solution, the method will eventually reach an inconsistent inequality.

One solution $\overrightarrow{S}$ within the bounds obtained by the resolution of the system is expressed in the Frame $\mathbb{B}$'s coordinates system. One can get the equivalent coordinates $\overrightarrow{S'}$ in the real world's coordinates system as follow:

$$\overrightarrow{S'} = \overrightarrow{O_{\mathbb{B}}} + C_{\mathbb{B}}.\overrightarrow{S} \tag{35}$$

Only one inconsistent inequality is sufficient to prove the absence of solution, and then the non intersection of the Frames. One shall check the inconsistence of each inequality as soon as possible during the resolution of the system to optimize the speed of the algorithm.

A suficient condition for one inequality $\sum_i a_i X_i \leq Y$ to be inconsistent is, given that $\forall i, X_i \in [0.0, 1.0]$:

$$Y < \sum_{i \in I^-} a_i \tag{36}$$

where $I^- = \{i, a_i < 0.0\}$.

3 Algorithms

In this section I introduce the algorithms of the solution of the previous section for the cases 2D and 3D.

3.1 2D case

algo

3.2 3D case

  bool isIntersecting2D =
    FMBTestIntersection2D(
      &P2D,
      &Q2D,
      &bdgBox2D);

  // If the two objects are intersecting
  if (isIntersecting2D) {

    printf("Intersection detected in AABB ");
    AABB2DPrint(&bdgBox2D);
    printf("\n");

  // Else, the two objects are not intersecting
  } else {

    printf("No intersection.\n");

  }

  return 0;
}
```

5 Validation

In this section I introduce the code I've used to validate the algorithm and its implementation. The validation consists of, first running the algorithm on a set of unit test for which the solution has been computed by hand, and second running the FMB algorithm on randomly generated pairs of Frame and check that its result is equal to the one of running the SAT algorithm on the same pair of Frames. The code of the implementation of the SAT algorithm is given in annex (p.116)

5.1 Code

5.1.1 Unit tests

```
// Include standard libraries
#include <stdlib.h>
#include <stdio.h>
#include <stdbool.h>

// Include FMB algorithm library
#include "fmb2d.h"
```

```
#include "fmb3d.h"

// Epslon for numerical precision
#define EPSILON 0.0001

// Helper structure to pass arguments to the UnitTest function
typedef struct {
  FrameType type;
  double orig[2];
  double comp[2][2];
} Param2D;
typedef struct {
  FrameType type;
  double orig[3];
  double comp[3][3];
} Param3D;

// Unit test function
// Takes two Frame definitions, the correct answer in term of
// intersection/no intersection and the correct bounding box
// Run the FMB intersection detection alogirhtm on the Frames
// and check against the correct results
void UnitTest2D(
        const Param2D paramP,
        const Param2D paramQ,
         const bool correctAnswer,

5.2.2 3D

6 Qualification

In this section I introduce the code I've used to qualify the algorithm and its implementation. The qualification consists of running the FMB algorithm

on randomly generated pairs of Frame, and check its execution time against the one of running the SAT algorithm on the same pair of Frames.

6.1 Code

```
// Include standard libraries
#include <stdlib.h>
#include <stdio.h>
#include <stdbool.h>
#include <time.h>
#include <sys/time.h>

// Include FMB and SAT algorithm library
#include "fmb2d.h"
#include "fmb3d.h"
#include "sat.h"

// Espilon for numerical precision
#define EPSILON 0.0001
// Range of values for the random generation of Frames
#define RANGE_AXIS 100.0
// Nb of run
#define NB_RUNS 1
// Nb of tests per run
#define NB_TESTS 1000000
// Nb of times the test is run on one pair of frame, used to
// slow down the processus and be able to measure time
#define NB_REPEAT_3D 800
#define NB_REPEAT_2D 1500

// Helper macro to generate random number in [0.0, 1.0]
#define rnd() (double)(rand())/(double)(RAND_MAX)

// Helper structure to pass arguments to the Qualification function
typedef struct {
  FrameType type;
  double orig[2];
  double comp[2][2];
} Param2D;
typedef struct {
  FrameType type;
  double orig[3];
  double comp[3][3];
} Param3D;

// Global variables to count nb of tests resulting in intersection
// and no intersection, and min/max/total time of execution for each
double minInter;
double maxInter;
double sumInter;
unsigned long countInter;
double minNoInter;
double maxNoInter;
double sumNoInter;
unsigned long countNoInter;

// Qualification function
// Takes two Frame definition as input, run the intersection test on
```

```
// them with FMB and SAT, and measure the time of execution of each
void Qualification2D(
        const Param2D paramP,
        const Param2D paramQ) {

  // Create the two Frames
  Frame2D P =
    Frame2DCreateStatic(
      paramP.type,
      paramP.orig,
      paramP.comp);

  Frame2D Q =
    Frame2DCreateStatic(
      paramQ.type,
      paramQ.orig,
      paramQ.comp);

  // Helper variables to loop on the pair (that, tho) and (tho, that)
  Frame2D* that = &P;
  Frame2D* tho = &Q;

  // Loop on pairs of Frames

7 Conclusion

The validation proves that the FMB algorithm correctly identifies intersection of pairs of Frames in accordance with the results of the SAT algorithm.

The qualification proves that the FMB algorithm is in average 50% slower than the SAT algorithm in 2D, and 17% faster in 3D.

8 Annex

8.1 SAT implementation

In this section I introduce the code of the implementation of the SAT algorithm, used to validate and qualify the FMB algorithm.

8.1.1 Header

```
#ifndef __SAT_H_
#define __SAT_H_

#include <stdbool.h>
```

```
#include <string.h>
#include "frame.h"

// ------------- Functions declaration -------------

// Test for intersection between 2D Frame 'that' and 2D Frame 'tho'
// Return true if the two Frames are intersecting, else false
bool SATTestIntersection2D(
  const Frame2D* const that,
  const Frame2D* const tho);

// Test for intersection between 3D Frame 'that' and 3D Frame 'tho'
// Return true if the two Frames are intersecting, else false
bool SATTestIntersection3D(
  const Frame3D* const that,
  const Frame3D* const tho);

#endif
```

8.1.2 Body

```
#include "sat.h"

// ------------- Macros -------------

#define EPSILON 0.0000001

// ------------- Functions declaration -------------

// Check the intersection constraint along one axis
bool CheckAxis3D(
  const Frame3D* const that,
  const Frame3D* const tho,
  const double* const axis);

// ------------- Functions implementation -------------

// Test for intersection between 2D Frame 'that' and 2D Frame 'tho'
// Return true if the two Frames are intersecting, else false
bool SATTestIntersection2D(
  const Frame2D* const that,
  const Frame2D* const tho) {

  // Declare a variable to loop on Frames and commonalize code
  const Frame2D* frameEdge = that;

  // Loop to commonalize code when checking SAT based on that's edges
  // and then tho's edges
